Control of a Microgrid in Islanded Mode

A thesis submitted in partial fulfillment of the requirements for the degree of Bachelor of Engineering
at
Murdoch University, Australia

November, 2012

Student name: Faisal Aljawder (30857509)

Supervisor: Dr. Gregory Crebbin

Acknowledgments

First, I would like to express my sincere gratitude to my supervisor, Dr. Gregory Crebbin, for his skilled guidance, assistance and support during the course of this project. Dr. Crebbin continually gave me comments and advice that helped me to overcome the difficulties that I encountered during the implementation of the project. Any time I faced a challenge, Dr. Crebbin was there to help, despite his busy schedule. Also, I am grateful to all the lecturers and tutors in the School of Engineering and Energy for their constant support and assistance throughout my engineering course.

Finally, I would like to thank my family and all my friends back home for their encouragement and support during the time that I stayed in Australia.

Abstract

Economic, technological and environmental issues are affecting the electrical power generation and transmission. A microgrid is a new technique that can provide electricity with less impact on the environment and is, at the same time, economically attractive. Basically, the concept of a microgrid is to use small-scale renewable generator sources instead of upgrading the main utility grid. This thesis presents a complete microgrid model and investigates the operational behaviour by using simulation software. The proposed control strategy described in this thesis is based on controlling the generators' output power to match the required power from the loads. This can be achieved by using the active vs. reactive power droop control method, which will make each generator independently controlled. In other words, the generators' output will adjust without requiring any data from other microgrid components. The main advantage of this technique is it increases the security and stability of the system by providing a supply of backup energy for the load in case one of the distributed generators shuts down.

If there is no synchronous machine to balance between supply and demand under microgrid disconnected mode, the inverters must take the responsibility of controlling the voltage and frequency. The voltage source control method that uses the P/Q Droop control technique is used in this thesis. The results proved that the P/Q droop control method is able to provide the loads with the required power and at the same time maintain the voltage and frequency within acceptable limits during island operation mode.
